Abstract: In the past 30 years, minimally invasive techniques in gynecology have developed rapidly. In order to carry out the concept of minimally invasive, improve the advantages of laparoscopic surgery, laparoendoscopic single site (LESS) surgery was widely recognized and rapidly developed. We describe a patient with adenomyosis of the uterus, who was treated by a single-port laparoscopic approach. A 50-year-old female with vaginal bleeding of more than half year, the ultrasound showed: adenomyosis. The blood routine examination suggested moderate anemia. Diagnosed with adenomyosis and anemia. The medicine was poor effective. We treated her surgically by a single-port laparoscopic approach. She recovery well after the surgery and no bleeding during follow-up. LESS was a new option of minimally invasive surgery. It brought rapid recovery. The surgery has several technical difficulties for doctor to master. We adopted an integrated mirror with optical fiber camera and used different lengths of surgical devices to reduce the mutual interference. Suturing and knotting was more difficult. Our solution was straight needle and vertical suturing. we used a right-angle forceps to create a “small operating triangle” to make the operation easier. LESS was a feasible method for the treatment of adenomyosis. The difficulty of the new surgery might figure out by several details.

Keywords: Laparoendoscopic single site surgery (LESS surgery); adenomyosis; abnormal uterine bleeding (AUB); case report

uterine myoma and adenomyosis showed LESS is not inferior to multi-port LH in terms of conversion and/or complications rates, including transfusion. The main disadvantage was that all surgical devices in a single site. Due to limited operation space and lacking of triangulation, the devices produce “chopstick effect” (7). It takes a lot of practice to master the operation skillfully (8). In this case, we performed hysterectomy and bilateral salpingectomy under LESS (Video 1). We mainly want to share our surgical skills, which may overcome the difficulties and defects of single-port laparoscopic surgery, the ultimate goal was reducing the surgical risk, and ensuring the surgical effect.

We present the following case in accordance with the CARE reporting checklist (available at http://dx.doi.org/10.21037/gpm-20-64).

Case presentation

A 50-year-old female was admitted to hospital for “vaginal bleeding for 7 months, aggravated for 2 days”, she developed vaginal bleeding about 7 months ago, the quantity was 2 times of ordinary menstruation. The ultrasound showed: adenomyosis, the thickness of endometrium was 7 mm. Hysteroscopy showed no obvious abnormalities, endometrial pathology revealed: endometrial hyperplasia. She was treated with levonorgestrel-releasing intrauterine system (LNG-IUS). There was no improvement in symptoms. Two months ago, the LNG-IUS was taken out, combined oral contraceptive (Yasmin) was taken. But the amount of withdrawal bleeding was more than 2 times of the normal menstrual. After admission, the ultrasound showed: adenomyosis, the thickness of endometrium was 5 mm. The blood routine examination suggested moderate anemia, the diagnosis was abnormal uterine bleeding-adenomyosis (AUB-A), and moderate anemia. The operation was performed on August 10. Operation manner: single-port LH and bilateral salpingectomy. Operation time: 1 hour and 45 minutes, intra-operative blood loss: 30 mL. Gastrointestinal function recovered at 18 hours after the operation. Pathology showed: adenomyosis, endometrial hyperplasia. Three days after the operation, the patient was discharged from hospital. She no longer experienced bleeding till now.

All procedures performed in studies involving human participants were in accordance with the Helsinki Declaration (as revised in 2013). Informed consent was obtained from the patient for publication of this manuscript and any accompanying images.

Surgical technique

After general anesthesia, the patient underwent the surgery in a cystolithotomy position. We set the buttocks higher than the head. Then made the longitudinal incision at the middle of navel about 1.5–2 cm. The single-port access platform (Figure 1A) was inserted into the abdomen under direct view, and CO₂ was charged. Intra-peritoneum pressure was maintained at 10–12 mmHg.
Before laparoscopic surgery, the uterine manipulation (Figure 1B) was placed into the cervix from the vagina. Uterine manipulation is helpful to expose the operation field, reduce the risk of ureter injury and reduce the difficulty of circumferential vaginal fornix. The surgical exploration of the pelvic and abdominal cavity revealed that the uterus was full, enlarged to 10+ weeks gestation, no adhesion, no abnormalities in bilateral adnexa. After double-check electrocoagulate mesosalpinx and isthmus of fallopian tube, bilateral fallopian tubes were transected with ultrasonic scalpel. The round ligament and utero-ovarian ligament was cut off at 2-cm point from the uterus attachment points (C); the anterior and posterior lobes of the broad ligament were separated laterally and stratified to the level of isthmus (D). (Figure 3). Repeatedly wash pelvic cavity and abdominal cavity and observe peristalsis of the ureter.

The timeline of the patient's clinical course depicted in Figure 4 and the clinic-pathologic data is depicted in Figure 5.

Discussion

In 1969, Wheeless (9) firstly reported 25 patients were surgically sterilized by electrocauterization and excision of a portion of each fallopian tube through the fiber optic laparoscopic, it marked the beginning of the era of LESS. In 1992, Pelosi (10) firstly reported LESS for multiple organs surgery, it's the first systematic description of trans-umbilical single-site laparoscopic surgery has the advantages of simplicity, reduction of trocar related complications. It also suggests the possibility of transit to standard laparoscopy or open surgery. In 2013, Song (11) reported 21 cases of single-port access total LH for large uterus, the result showed LESS for large uterus is a feasible and safe technique. After nearly 30 years of development, LESS can complete most gynecological surgery, but there's not enough evidence-based medical evidence to prove its
Figure 3 The bladder was pushed down from the lower uterine, cervix, and the upper 1 cm of the vagina (A); the uterine vessels were cut off by ultrasonic scalpel after sutured by 2-0 stitches at the level of isthmus (B); the vagina was cut off by vaginal fornix (C); the vaginal wall was closed by suturing intermittently (D).

safety and effectiveness. In 2011, a review (12) about LESS show improvements in traditional laparoscopic techniques and availability of more advanced instruments has made LESS more feasible and safer for the patient. Although LESS surgery provides another option in the arena of minimally invasive gynecologic surgery, the ultimate role of this approach remains to be determined, under the current medical conditions, benign disease should be the main indication of LESS (13,14). However, LESS has its inherent limitations (14); for example; the operating triangle is lost, interference between operating instruments (15), the limits of vision, special learning curve, here we report a case of modified surgical procedures and techniques to overcome the inherent limitations in LESS, successful completed the surgery of total hysterectomy and bilateral salpingectomy for a patient with AUB-A, the operation take 1 hour 45 minutes, 30 mL of intraoperative bleeding, no complications, the operation was satisfactory.

(I) Single-port laparoscopic surgery has unique technical difficulties, such as the mutual interference of surgical devices, the limitation of operating triangulation, and so on (16). Especially the interference between surgical devices, knowing as the “chopstick effect”, makes the surgery more difficulty. In order to reduce the mutual interference between the surgical devices, we adopted an integrated mirror with optical fiber camera to reduce the interference between the optical fiber and the operator, and used different lengths of surgical devices to reduce the mutual interference between the them (Figure 6).

(II) The ascending branch of the uterine artery is attached to the uterine lateral wall, in order to avoid damaging the branches of the uterine artery and reducing

Figure 5 Ultrasound on 30/01/2020 showed: adenomyosis, the thickness of endometrium was 7 mm, endometrial (A); pathology on 31/01/2020 showed endometrial hyperplasia, H&E, x20 (B); ultrasound on 08/08/2020 showed: adenomyosis, the thickness of endometrium was 5 mm (C); pathology on 13/08/2020 showed adenomyosis, endometrial hyperplasia, H&E, x20 (D).
the intra-operative bleeding. We can inherent the round ligament, fallopian tubes and utero-ovarian ligament away from the uterus, the distance should more than 3 cm (Figure 7). The mesosalpinx of fallopian tube is rich in vascular plexuses, before transect fallopian tube, carefully electric coagulate is necessary. Considering the accurate hemostatic effect, uterine vessel should be stitched before transected, also can reduce the risk of re-opening of the postoperative blood vessel ending.

(III) Suturing and knotting is the basic of surgical operation. Proficient in using the technology was essential for the operation (17). The LESS operation is deficient in “operating triangle”. So, the devices may interfere each other. It is very difficult to suture and knot under single-port laparoscopic surgery, that is the main reason which constraint the development of LESS. Our solution to this problem is straight needle and vertical suturing, which we suppose, may effectively overcome these difficulties and ensure the completion of the suturing. When it comes to tying the knot, we used a right-angle forceps to create a “small operating triangle” to make it easier (Figure 8).

Conclusions
LH and bilateral salpingectomy were a main therapy for adenomyosis, which was poor effect to medicine treatment. For the requirement of rapid recovery and cosmetic results, single-port laparoscopic approach may be a better choice. The greatest difficulty of LESS is the limitation of operating space. We adopted an integrated mirror with optical fiber camera to reduce the interference, and used different lengths of surgical devices. we used a straight needle to suture and right-angle forceps to knot. These surgical skills may overcome the difficulties and defects of single-port laparoscopic surgery, could make the operation more convenient. But the ultimate role of this approach

remains to be determined.
